DRAINAGE PLAN
HOOVER INDUSTRIAL PARK ADDITION

MARCH 2014

REPORT CONTENTS

EXISTING CONDITIONS

The property is approximately 73 acres located along the south side of K96 Highway and adjacent to Hoover Road in northwest Wichita. The property is currently farmland with farmland to the south and a C&D Landfill to the east.

The site appears to have standing water after rainfall events as well as the property to the south. The overall overflow of the site is to the north east and into the KDOT K96 ROW. The overall drainage patterns of this site as well as the rest of the basin is very flat with high infiltration rates.

The drainage patterns can be viewed on the Aerial and Lidar Exhibit (Exhibit 1).

PROPOSED CONDITIONS

The proposed property is being platted as an industrial park that will feature 36 large industrial lots with an internal street loop and a detention/retention facility. We expect the individual lots to have large buildings with paved and gravel parking. The lots are expected to drain primarily to the rear drainage easements and into proposed drainage ditches/channels. The grassed lined channels will provide some water quality and inherent detention for the site before being treated further and then discharged into the groundwater pit.

For a half-scale copy of the Plat, see Exhibit 2.

OFFSITE CONDITIONS

This basin, including this site, is very flat and appears to stand water during and after rainfall events. There is a small ditch section on the south side of K96 that appears to drain the ROW and cross road pipes under K96. This ditch flows to the east along K96 and then to the east. This ditch appears to lose conveyance approximately 1 mile to the east around the West Street off ramp(s).

There is approximately 23 acres of farmland and pasture that drains onto this site from the south and south west. A small portion of this site near the eastern half of the south line appears to drain onto the south property where it likely stands before infiltrating.

The Offsite Drainage Exhibit can be seen as Exhibit 6.

There does not appear to be any runoff encroaching this property from the north as the culverts under K96 drain into the KDOT ROW ditch section. This ditch is located north of the property and fence line and appears to be well defined along the north line of the property.

EXISTING CONDITIONS RUNOFF CALCULATIONS

DRAINAGE METHODS & STANDARDS

The following methods and standards, although not a complete list, were used in calculating the existing conditions runoff values.

- STORM SERIES
  - 24-hour; 2-yr, 5-yr, 10-yr, 25-yr, 100-yr Storm Events
  - 2-yr Rainfall Intensity = 3.83 in
  - 10-yr Rainfall Intensity = 5.22 in
  - 100-yr Rainfall Intensity = 7.37 in

- FLOW DATA
  - Areas per LIDAR data, USGS Quadrangle Sheet, Aerial Photos, and Site Visits
  - SCS Curve Number Method (CN = 71)
  - Time of Concentration: Lag Method (minimum 15 min)

SITE CHARACTERISTICS

The site is currently farmland and is very flat – as is the entire basin in this area. The site does drain a small portion to the south and onto the south adjacent property as well as to the north east and into the KDOT ROW ditch. The remainder of the site has ponding areas and appears to infiltrate into the sandy soils. The site accepts some offsite flow from the south where it appears to pond along the south property line – on this site as well as the south property.

EXISTING CONDITIONS HYDROLOGIC ANALYSIS

This property was analyzed based on existing conditions for peak runoff values for the entire storm series. Conditions on the site are farmed pasture in Type B soils (a composite of Types B, C, & D soils – underlying soils on the site are sandy, based on NRCS Soil Survey). A minimum Time of Concentration of 15 minutes was used, where applicable. The SCS Curve Number method was used for peak flow rates with a Curve Number of 71 (Undisturbed/ Pre-developed).

DOWNSTREAM DRAINAGE CAPACITY

The basin ultimately drains to the east and to the Arkansas River. There is currently a roadside ROW ditch on the south side of K96 that drains to the east. This ditch appears to be fade out approximately 1 mile to the east near the West Street ramps. There does not appear to be much additional capacity in the ROW ditch for anything other than the cross road pipes from the north and the KDOT ROW. A portion of this site drains and ponds to the south near the south east corner of the property. This area is intended to drain - eventually – to the south across this property and to 37th Street. There is major ponding and infiltration to the south as well as on the subject property.

POST-DEVELOPMENT HYDROLOGIC ANALYSIS

DRAINAGE METHODS & STANDARDS

The following methods and standards, although not a complete list, were used in developing the drainage and grading plans.

- STORM SERIES
  - 24-hour; 2-yr, 5-yr, 10-yr, 25-yr, 50-yr, 100-yr Storm Events Calculated
  - Rational Formula Method used for peak runoff
  - CN = 93 (Composite of Impervious and Disturbed Areas)
  - Time of Concentration; Lag Method, minimum Tc = 15min
  - Ditches sized for 100-year event.
  - Hydroguard Units sized for 1.2" rainfall

- GRADING CONSTRAINTS TO BE OBSERVED AT SITE PLAN
  - One foot freeboard between 100-yr WSE and adjacent lot corner
  - Match all existing perimeter grades

DEVELOPED CONDITIONS HYDROLOGIC ANALYSIS

The site is being platted into 30 industrial lots with a loop street and associated utilities and detention/retention groundwater pit. The site was analyzed for runoff values based on approximately 72% impervious cover in Type B soils. The site was divided into sub-basins in order to size drainage channels and water quality structures.

Time of concentration for each sub-basin was computed using the proposed channel slope and cross section as well as proposed cover type. The Curve Number Method was used for total flows using a CN of a 93. This CN was based on industrial cover (72% impervious) in Type B soils. It should be noted that once this site is mass graded using the overburden from the detention facility that this soil type would lean more towards a Type A as this area is sandy.

The proposed channel sections were modeled as reaches in HydraFlow based on channel geometry with a slope of 0.2%. These ditches were not modeled for infiltration although we expect a high level of infiltration with the geometry and relatively flat slope of the channel bottom. The ditches do have some inherent detention, although not directly accounted for, whereas when modeled as a reach the peak flow is drawn down due to longer times of concentration.

DETENTION FACILITY

There is one proposed facility located in this subdivision located at the east end of the property. The detention pond will be located in groundwater and will be a pure retention facility with no true outfall. The pond is described in more detail below.

Reserve A

The pond in Reserve A will be in groundwater and will be approximately 5 acres in surface area at its static elevation of 1323.0. The pond will accept runoff from this entire developed site as well as the 23 acres of offsite flow from the south. The pond will not have a defined overflow or discharge

structure although the north east corner of the Reserve will be left at a 1330 elevation to allow for overtopping into the KDOT ROW.

Since the pond will be in groundwater, water quality will be required prior to any runoff entering. This will done by using the grass lined channel sections to get 50% removal and then using Hydroguard units to further clean the runoff before being discharged. We expect full retention of the storm series expect a small amount, approximately 6 cfs, to be discharged in the 100-year storm event at approximately 2 inches in flow depth. Since this is a groundwater pit, we would not expect the water surface to stay elevated at the peak elevation for more than 4 days. Also, since this is groundwater, these figures are conservative as runoff will likely infiltrate into the groundwater basin and not surcharge the pond as much as the model portrays.

DISCHARGE POINTS SUMMARY

The site currently drains a portion to the south east onto the south adjacent property as well as overflowing to the north east and into the KDOT ROW ditch. We do not expect to discharge any runoff to the south as this plat will utilize its own detention area for storage. The proposed pond is expected to discharge to the north and into the ROW only during the 100-year and larger storm events. This pond is a groundwater pit and would otherwise not have a discharge.

WATER QUALITY

Water quality will be obtained on this industrial plat prior to discharging into the groundwater pit. This will be achieved utilizing the grass lined drainage ditches/channels to achieve a portion of the treatment. Typically, the grassed lined channels can treat up to 50% of the TSS removal. In this case, the grassed lined channels will be relatively flat at 0.2% with a wide 5' bottom in a sandy soil. This channel, with these characteristics, will also have a high infiltration rate which would help us achieve more than the 50% removal rate – the channels would function more like an enhanced swale. For this project, however, we will assume only the 50% TSS removal from the ditch/channel sections and further treat the remainder of the flow with a water quality unit located at the very downstream end to the channel before entering the ground water pit. This unit will be sized to treat the remainder, approximately 30%, of each respective basins water quality flow.

DOWNSTREAM CHANNEL PROTECTION

Since this property will have a true non-discharging ground water lake, the downstream channel protection volume will be absorbed into the pit. We do not expect any discharge during the channel protection 1-year storm event.

POTENTIAL UPSTREAM/DOWNSTREAM IMPACTS

Due to the size of the retention facility with little to no discharge throughout the storm events, we do not expect any downstream impacts. This plat will accept all offsite runoff and we expect no upstream impacts. It appears that there is standing

water on the site as well as the surrounding properties. With the construction of this pit we expect this to help some of the basins flooding issues.

Since we are treating the runoff before entering the groundwater pit, we do not expect any impacts to the surrounding or downstream water table with this development.

SOURCE OF FLOODPLAIN INFORMATION

This site lies within a FEMA Zone X per FEMA FIRM Panel 195 of 700 for Wichita, Sedgwick County, Kansas; effective February 2, 2007.

FEDERAL, STATE, & LOCAL PERMITTING

US ARMY CORPS OF ENGINEERS

There does not appear to be any jurisdictional waters of the US on this site.

KANSAS DEPT OF AGRICULTURE – DWR PERMITTING

There does not appear to be any DWR permitting needed on the proposed site at this time. The areas of discharge do not account for more than 640 acres.
Since this is a groundwater pit, a groundwater appropriations permit application will need to be filed and approved for the construction of the open water.

FEMA

No FEMA permitting is expected at this time.

KANSAS DEPT OF TRANSPORTATION

There is no KDOT ROW adjacent or near this property which would require a permit at this time since there is no additional discharge into the ROW with this plat.

SEDGWICK COUNTY PERMITTING

There does not appear to be any Sedgwick County permitting needed at this time.

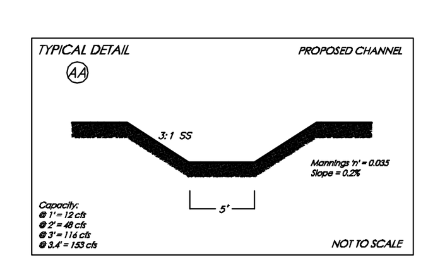
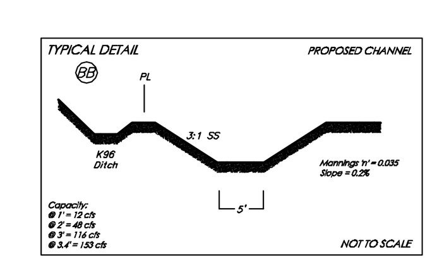
The above sub-basins are for sizing storm water sewer (where applicable) as well as the ditch/channel sections. Water quality and water quality treatment structures calculated and sized per total flows being conveyed to the 3 entrances to the groundwater pit.

X Proposed Flows at Point X	Y Proposed Flows at Point Y	Z Proposed Flows at Point Z
Q_2 = 25 cfs	Q_2 = 72 cfs	Q_2 = 53 cfs
Q_5 = 35 cfs	Q_5 = 98 cfs	Q_5 = 75 cfs
Q_{10} = 41 cfs	Q_{10} = 117 cfs	Q_{10} = 91 cfs
Q_{100} = 66 cfs	Q_{100} = 190 cfs	Q_{100} = 152 cfs

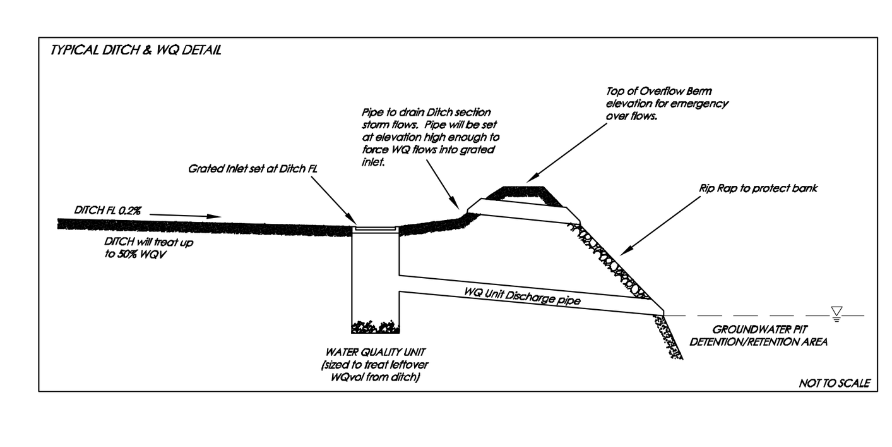
The above sub-basins and flows were modeled using the respective drainage basins and routed through a reach consisting of the proposed ditch section as shown per this plan. See HydraFlow model for additional details.





NOTE: Leave existing K96 ROW ditch intact for KDOT drainage from north. Onsite ditch will be utilized for this sites' flow to the detention facility.

Although the onsite soils will allow a large amount of infiltration, ditch sections were not modeled as having infiltration. This is a conservative approach as the infiltration will also allow some water quality treatment as well as reducing the peak flow to the qater quality unit and groundwater pit.



NOTES: There is no FEMA SFHA located on this property as of this date per FEMA FIRM Panel 195 of 700, for Wichita, Sedgwick County, Kansas; effective February 2, 2007.

MAP INFORMATION

The soil surveys that comprise your AOI were mapped at 1:24,000.

Warning: Soil Map may not be valid at this scale.

Enlargement of maps beyond the scale of mapping can cause misunderstanding of the detail of mapping and accuracy of soil line placement. The maps do not show the small areas of contrasting soils that could have been shown at a more detailed scale.

Please rely on the bar scale on each map sheet for map measurements.

Source of Map: Natural Resources Conservation Service
Web Soil Survey URL: http://websoilsurvey.nrcs.usda.gov
Coordinate System: Web Mercator (EPSG:3857)

Maps from the Web Soil Survey are based on the Web Mercator projection, which preserves direction and shape but distorts distance and area. A projection that preserves area, such as the Albers equal-area conic projection, should be used if more accurate calculations of distance or area are required.

This product is generated from the USDA-NRCS certified data as of the version date(s) listed below.

Soil Survey Area: Sedgwick County, Kansas
Survey Area Data: Version 9, Dec 10, 2013

Soil map units are labeled (as space allows) for map scales 1:50,000 or larger.

Date(s) aerial images were photographed: Jul 18, 2010—Sep 27, 2011

The orthophoto or other base map on which the soil lines were compiled and digitized probably differs from the background imagery displayed on these maps. As a result, some minor shifting of map unit boundaries may be evident.

Description

Hydrologic soil groups are based on estimates of runoff potential. Soils are assigned to one of four groups according to the rate of water infiltration when the soils are not protected by vegetation, are thoroughly wet, and receive precipitation from long-duration storms.

The soils in the United States are assigned to four groups (A, B, C, and D) and three dual classes (A/D, B/D, and C/D). The groups are defined as follows:

Group A. Soils having a high infiltration rate (low runoff potential) when thoroughly wet. These consist mainly of deep, well drained to excessively drained sands or gravelly sands. These soils have a high rate of water transmission.

Group B. Soils having a moderate infiltration rate when thoroughly wet. These consist chiefly of moderately deep or deep, moderately well drained or well drained soils that have moderately fine texture to moderately coarse texture. These soils have a moderate rate of water transmission.

Group C. Soils having a slow infiltration rate when thoroughly wet. These consist chiefly of soils having a layer that impedes the downward movement of water or soils of moderately fine texture or fine texture. These soils have a slow rate of water transmission.

Group D. Soils having a very slow infiltration rate (high runoff potential) when thoroughly wet. These consist chiefly of clays that have a high shrink-swell potential, soils that have a high water table, soils that have a claypan or clay layer at or near the surface, and soils that are shallow over nearly impervious material. These soils have a very slow rate of water transmission.

If a soil is assigned to a dual hydrologic group (A/D, B/D, or C/D), the first letter is for drained areas and the second is for undrained areas. Only the soils that in their natural condition are in group D are assigned to dual classes.

Rating Options

Aggregation Method: Dominant Condition

Aggregation is the process by which a set of component attribute values is reduced to a single value that represents the map unit as a whole.

A map unit is typically composed of one or more "components". A component is either some type of soil or some nonsoil entity, e.g., rock outcrop. For the attribute being aggregated, the first step of the aggregation process is to derive one attribute value for each of a map unit's components. From this set of component attributes, the next step of the aggregation process derives a single value that represents the map unit as a whole. Once a single value for each map unit is derived, a thematic map for soil map units can be rendered. Aggregation must be done because, on any soil map, map units are delineated but components are not.

For each of a map unit's components, a corresponding percent composition is recorded. A percent composition of 60 indicates that the corresponding component typically makes up approximately 60% of the map unit. Percent composition is a critical factor in some, but not all, aggregation methods.

The aggregation method "Dominant Condition" first groups like attribute values for the components in a map unit. For each group, percent composition is set to the sum of the percent composition of all components participating in that group. These groups now represent "conditions" rather than components. The attribute value associated with the group with the highest cumulative percent composition is returned. If more than one group shares the highest cumulative percent composition, the corresponding "tie-break" rule determines which value should be returned. The "tie-break" rule indicates whether the lower or higher group value should be returned in the case of a percent composition tie. The result returned by this aggregation method represents the dominant condition throughout the map unit only when no tie has occurred.

Component Percent Cutoff: None Specified

Components whose percent composition is below the cutoff value will not be considered. If no cutoff value is specified, all components in the database will be considered. The data for some contrasting soils of minor extent may not be in the database, and therefore are not considered.

Tie-break Rule: Higher

The tie-break rule indicates which value should be selected from a set of multiple candidate values, or which value should be selected in the event of a percent composition tie.
